Web3, Blockchain & Crypto: Rewriting the Rules of the Digital Game!

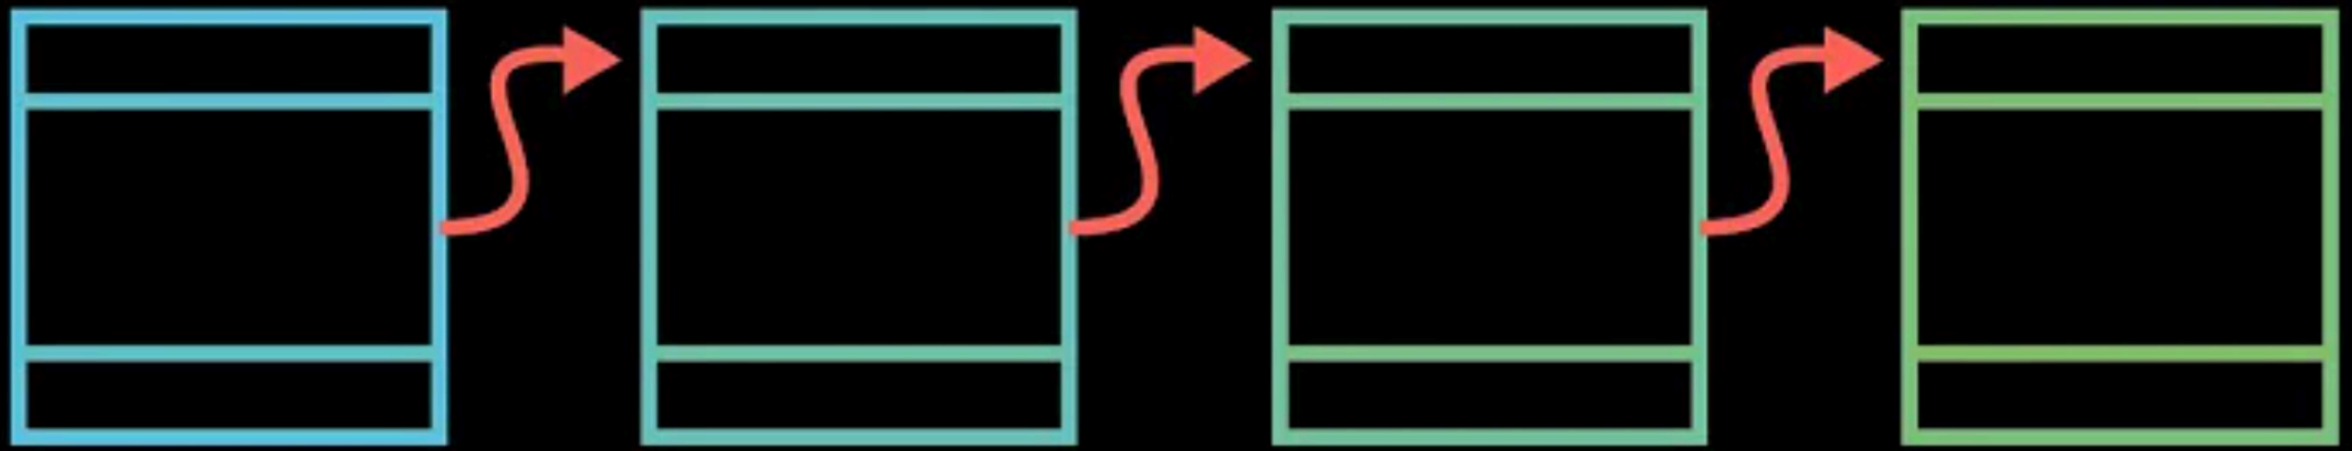

WEB 1 → **WEB 2** → **WEB 3**

What is Blockchain?

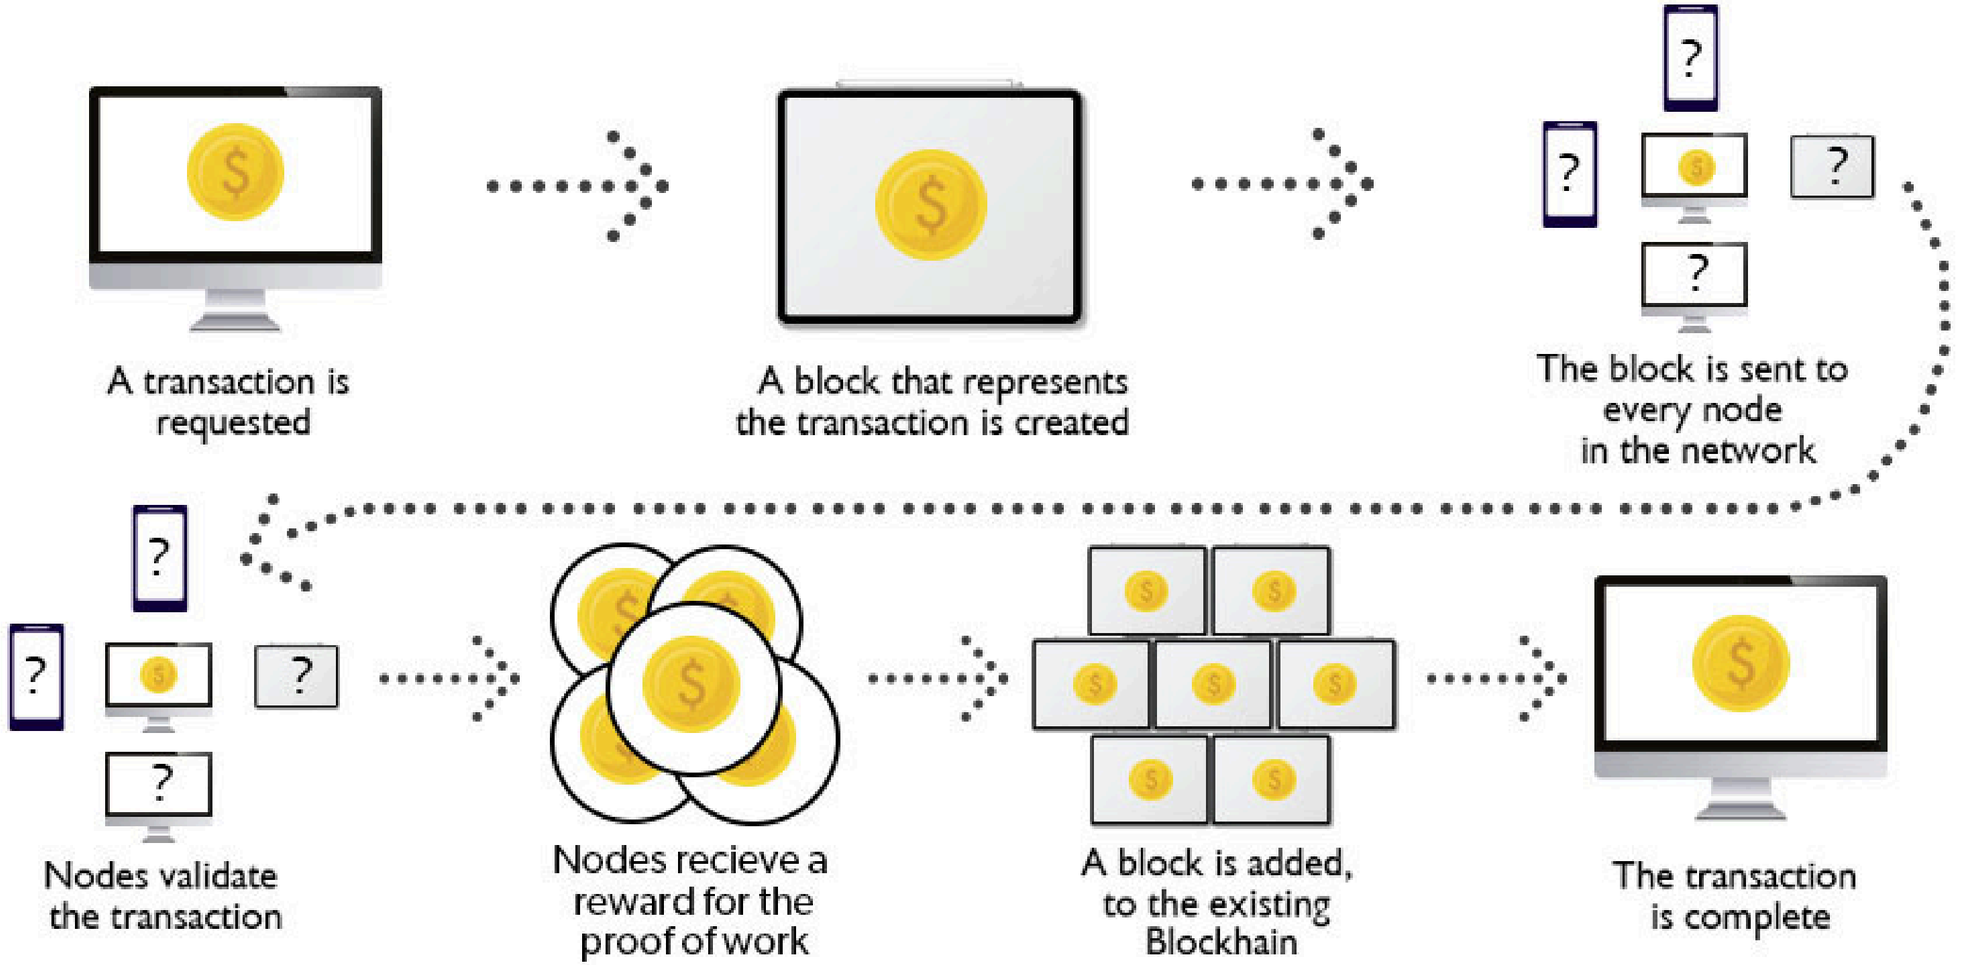

- A decentralized, distributed ledger technology.
- Stores data in blocks chained together.
- Provides transparency, immutability, and security.

Why it matters?

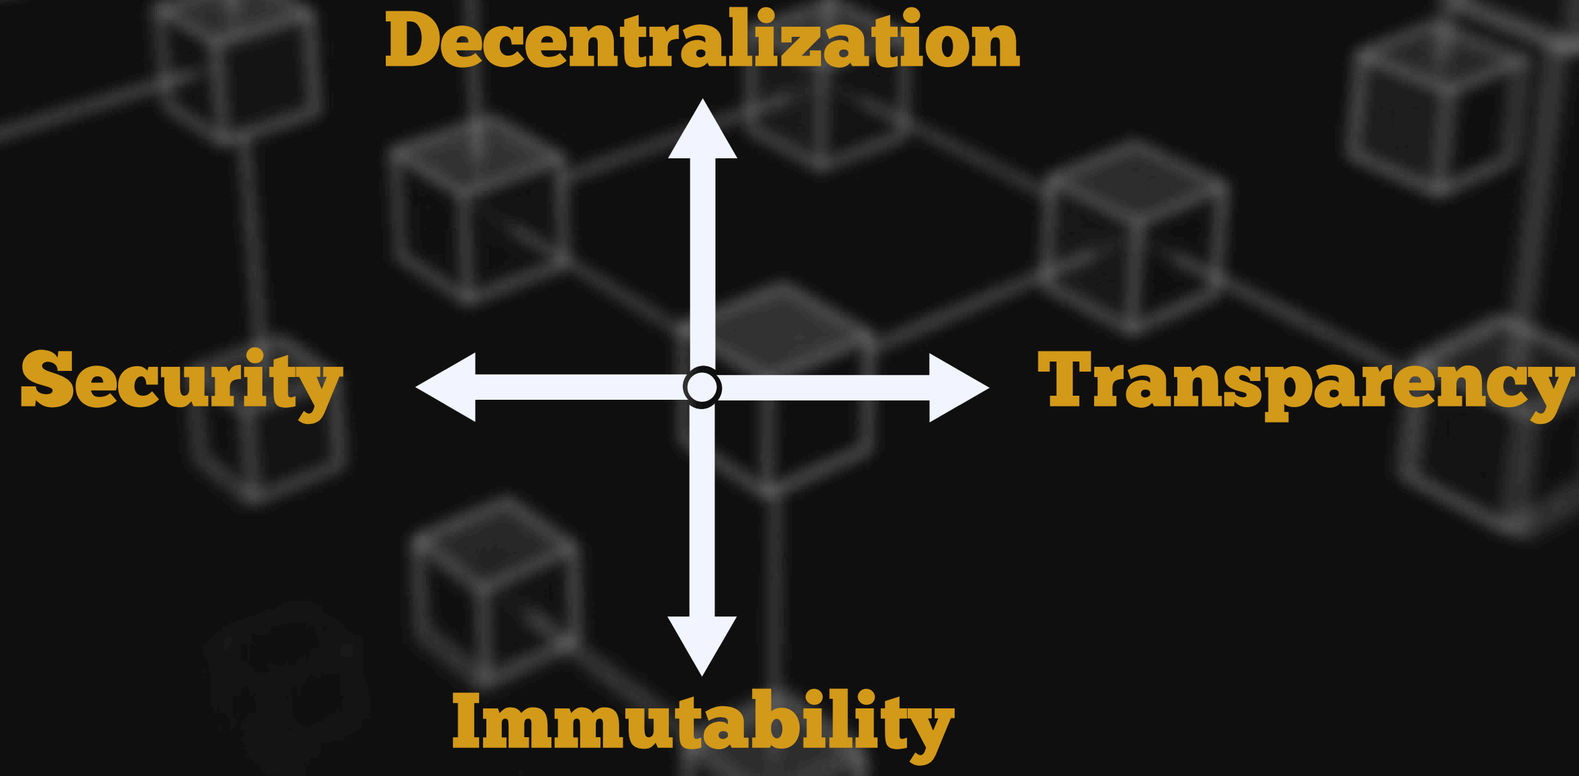

- Eliminates the need for intermediaries.
- Improves trust and efficiency in transactions.
- Growing adoption in various industries.

How Blockchain Works?

Key features of Blockchain

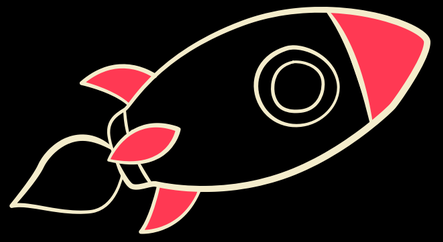

CRYPTOCURRENCY

- Cryptocurrency is digital money that operates on a technology called blockchain, which allows people to send and receive payments without needing a bank or intermediary.

- Coins are digital currencies that are native to their blockchains. These coins are typically used as a form of currency or store of value.

- Token is a digital asset created on top of an existing blockchain Tokens are built using smart contracts on existing blockchains. Tokens are highly versatile.

immutable

transactions

digital "if-then"

Solidity: The Language of Smart Contracts

- Solidity is the programming language primarily used to write smart contracts on the Ethereum blockchain.
- Similar to JavaScript/C++
- Solidity supports variables, loops, conditionals, functions, and even inheritance
- Solidity code is compiled into bytecode and then executed by the Ethereum Virtual Machine (EVM).
